COMPARISON OF MUTANT P53 PROTEIN EXPRESSION IN PTERYGIUM GROUP WITH AND WITHOUT TRIAMCINOLONE ACETONITED INJECTION

ABSTRACT

Background: Mutant p53 protein is produced by mutant p53 gene, this protein takes part in tissue hyperplasia process in pterygium. Triamcinolone acetonide is often use to reduce reccurency. Besides decreasing the inflammation triamcinolone acetonide is assumed to be able to repair the function of p53 gene. Thus, it reactives cell apoptosis system and prevent the tissue hyperplasia process in pterygium. To compare Mutant p53 Protein Expression in Pterygium Group With and Without Triamcinolone Acetonide Injection

Methods: This research is a randomized clinical trial study consists of 31 subject who suffered primary pterygium. All subject divided into 2 grup with and without triamcinolone acetonide injection. After excision the pterygium and the tissue were examined through histopatology and immunohistochemical with Hematoxyline Eosin and reagent Clone DO7 staining to see the mutant p53 protein expression.

Results: Mutant p53 protein expression in triamcinolone acetonite injected group is 0% and non triamcinolone acetonite injected group is 33,33%.

Conclusion: Mutant p53 protein expression in triamconolone  injected group is lower than non injected group.

Keywords: Mutant p53 protein, primary pterygium, triamcinolone acetonide, immunohistochemical

ABSTRACT

Tujuan: Untuk membandingkan ekspresi reseptor Protein p53 mutan antara kelompok penderita pterigium yang diinjeksi triamsinolon asetat dan kelompok penderita pterigium tanpa injeksi triamsinolon asetat.

Hasil: Ekspresi protein p53 mutan pada kelompok penderita pterigium yang diinjeksi triamsinolon asetat 0% dan pada kelompok penderita pterigium tanpa injeksi triamsinolon asetat sebesat 33,33%.

Kesimpulan: Ekspresi protein p53 mutan pada kelompok penderita pterigium yang diinjeksi triamsinolon asetat lebih rendah dibandingkan dengan kelompok penderita tanpa injeksi triamsinolon asetat.

Kata Kunci: Protein p53 mutan, pterigium, triamsinolon asetat, imunohistokimia.

INTRODUCTION

Pterigium is a degeneration and hyperplasia process of fibrous tissue in the form of a triangle in the conjunctiva along the interpalpebral fissure with a centralized peak or in corneal region.\textsuperscript{1-8} Pterigium prevalence varies by race, age, gender, and geographic location. In Indonesia, the prevalence of pterygium in patients over 40 years old is 10%. Men has higher risk than women. In general, the prevalence of pterygium in the tropics is higher than in sub-tropics region. This occurs because exposure to ultraviolet (UV) rays in the tropics is higher than subtropical regions.\textsuperscript{1-12}

UV exposure can also cause damage to DNA causing inactivation of the p53 gene which is one of the gene suppressor tumors that play a role in controlling cell cycle, cell differentiation, and apoptosis.\textsuperscript{1-17} This is supported by several studies showing the abnormal expression of the mutant p53 protein in more than 50% of patients with pterygium.\textsuperscript{18-24} Management of pterygium is conservative and operative generally. Because of the high recurrence rate after excision as many as 24% to 89%, the operative is only performed on cases that cause visual disturbance, irritation that can not be reduced with medicamentosa, detention of eyeball movement due to pterygium growth.\textsuperscript{1,4-7}

Triamcinolone acetate, which is a synthetic corticosteroid, is thought to decrease pterygium recurrence. Triamcinolone acetate acts as an anti-inflammatory by inhibiting fibroblast forming activity, slowing epithelial and endothelial regeneration processes and reducing neovascularization after inflammation.\textsuperscript{13,14}

In cases of leukemia, lymphoma and myeloma, glucocorticoids used as chemotherapy to increase apoptosis in blood cells. Crochemore et al. conducted a study of nerve cells and found that steroid may activate glucocorticoid receptors that would increase p53 activity resulting inhibit in neural cell proliferation.\textsuperscript{25-27} Similarly, in pterygium, it is expected that corticosteroid, such as triamcinolone acetate before pterygium surgery can act as a therapeutic adjuvant to increase the level of wild-type p53 or decrease the expression of p53 mutant type protein, and there after may reduce pterygium recurrence after anti-metabolite or radiation therapy.

In Indonesia, especially in Palembang, study in evaluating of mutant p53 protein expression in pterygium patient which got triamnisolone acetate had been don yet. The aim of this study was to find out whether the expression of p53 mutants protein in the pterygium group injected triamcinolone acetate was lower than the expression of p53 mutant protein in the pterygium group without triamcinolone acetate injection.

MATERIAL AND METHODS

This study is randomized clinical trials study by single blinded form conducted in Reconstruction Subdivision Ophthalmology Departement FK UnsrI / RSMH Palembang, satelit hospital, and Pathology Anatomy Laboratory RSMH Palembang. This study conducted in April 2013 to August 2013 (until the number of samples was fullfill). The population was all primary pterygium patients who underwent primary pterygium excision with or without conjunctival graft which fulfilled inclusion and exclusion criteria and were willing to participate in this study. Samples were taken by consecutive sampling technique.

The inclusion criteria are all primary pterygium grade II patient or more who will undergo pterygium excision surgery at RSMH / Ophthalmology Departement satelit hospital. Exclusion criterion is pseudopterigium, history of topical steroid use at last 2 weeks ago. Drop out criteria if in sampling specimen is not sufficient for histopathological examination and patient is out of control 1 week after injection of triamcinolone acetate.
Procedure of Study
Patients with pterygium, who will undergo excision surgery, who fulfill sample criteria and willing to take part in the study, are divided into two groups by simple randomization. In the first group, a 0.2 ml triamcinolone acetate was administered in subconjunctiva 1 week before excision. After one week post-injection, excision of pterygium was performed. While in the second group, triamethinolone acetate injection was not performed prior to excision. Excision is performed in the operating room. After excision, the pterygium tissue previously marked on the superior and inferior parts of the limbus is inserted into a container containing 10% formaldehyde buffer solution, and sent to Pathology Anatomy laboratory for immunohistochemical assessment. Histopathologic and immunohistochemical assessments were performed by an Pathology Anatomy physician who did not know which group of treated sample.

Triamcinolone acetate injection procedure
1. The patient lies supine in an aseptic antiseptic condition.
2. The operator uses sterile gloves
3. 2% tetracaine imprinted on the conjunctiva
4. Blepharostat installed
5. Conjunctiva removed by using sterile conjunctival tweezers
6. 0.2 ml triamcinolone acetate was injected in subconjunctiva
7. chloramphenicol eye ointment is administered in conjunctiva and then conjunctiva is covered with sterile gauze.

Procedure of excision of pterygium with or without conjunctival graft.
1. The patient lies supine in an aseptic antiseptic condition.
2. The operator uses sterile gloves
3. topical anestheic is administered
4. Blepharostat is installed
5. Lidocaine HCl 2% is administered in subkonjungtiva on pterigium tissue till the head of pterygium in cornea. The base of the pterygium tissue is separated from sclera, separating the attachment in the limbus is done bluntly and sharply by using the Wescott scissors. The attachment of the pterygium in the cornea is released by peeling off the tissue toward the center of the cornea gently. Clean the limbus area and the pterygium residue in the cornea bluntly. The pterygium tissues in the superior and inferior limbus regions are marked with yarn. Bleeding is treated with a bandage or diathermy.

The procedure for pterygium excision with conjunctival autograft is done by interuptus stitching conjunctival graft in pterigium region with vicryl 8.0. Stitching must accompany suture sclera and attempted to bring together the edge of the incision conjunctiva as far as possible. eyes are given anti-biotic ointment and closed until the next day and the patient was given analgesics and a drops of steroid four times daily.

RESEARCH RESULT
The study involved 31 subjects consisting of 16 subjects with subconjunctiva triamcinolone acetate injection and 15 subjects without triamcinolone acetate injection. Characteristics of research subjects are shown in Table 1.

Gender
In this study, in the TA injection group, there were as many patients as male and female, 8 people, whereas in the group without TA injection there were 5 patients with male sex and 10 female patients. Statistical analysis showed that there were no
gender differences between patients with and without TA injection

**Occupation**

In this study patients working outdoors consisted of drivers, motorbike drivers, rickshaw pullers, farmers and charcoal makers while patients working indoors consisted of housewives, teachers/lecturers and civil servants. In the group with TA injection there were 11 people who worked outdoors while in the group without injection there were 7 people who worked outdoors. Statistical analysis showed that there were no occupation differences between patients with and without TA injection.

In addition, the expression of p53 mutants in patients who worked outdoors was lower than indoors but the difference was not statistically significant.

Staining of Mutant p53 at Pterygium Epithelial Nucleus Cell
DISCUSSION

Triamcinolone acetate is a synthetic glucorticoid that has anti-inflammatory effects. It has a moderate life time (12-36 hours) and does not cause sodium retention. Corticosteroids as anti-inflammatory have been known reduce the recurrence of pterygium. In some studies, the rate of pterygium recurrence of patients who receive adequate topical corticosteroid therapy was lower than in patients receiving inadequate topical corticosteroid therapy after pterygium surgery. Yaisawang et al got from 142 eyes pterygium who undergo surgery, there was 21 patients who experienced recurrence, 5 people of them received adequate topical corticosteroid therapy while 16 people of them with inadequate topical corticosteroid therapy after surgery. A 0.2 ml subconjunctiva of triamcinolone acetate may be injected to recurrence pterigium after surgery and may be repeated 3 times of 2 weeks interval.13,14

Handoko et al conducted a study which obtained 64 primary progressive pterygium, where there was a difference in the number of stained cells between the pterygium patient with triamcinolone acetate injection and pterygium patient without triamcinolone acetate injection.46 Study conducted by P Anguria et al in Lampopo concluded that people who have a family history suffered from pterygium had a risk of suffering from pterygium 3.93 times greater than those without a family history of suffering from pterygium. Whereas in a study conducted by Booth in Australia, there are 38% of patients with pterygium performed excision surgery had a family history of pterygium.47-49

In some studies, stated mutant p53 protein expression with cut off> 10% was associated with p53 gene mutation whereas mutant p53 protein expression with cut off <10% was associated with cell proliferation activity.21 To find out the influenced of gender in p53 expression in this study, Spearman's correlate analysis was done, which there was no relationship between gender with the number of stained cells (rho = 0.198, p = 0.286). Ueda et al reported in men has higher stained cells than women because the occupation of men mostly outdoors so more exposed to the sun. While in study conducted by Tsai in Taiwan, gender had no influence on p53 expression.

Study conducted by Hiroki et al reported different things where the prevalence of pterygium in men is greater than in women. In contrast, Gazzard et al and Durkin SR et al reported the same thing in which there was no significant difference in gender distribution of pterygium. 42-44 Farmers or workers in the plantation is the most occupation in this study as many as 13 subjects (40.62%). These is according to study which conducted by Gazzard et al, Durkin SR and Hiroki et al They are explaining that outdoor work has higher risk to pterygium events. Meanwhile, according to Rajiv Luthra et al people who work outdoors have a risk 1.87 times to suffer from pterygium compared to people working indoors.

This study evaluate this time it is only used after (injection of subconjunctival triamcinolone acetate one week before surgery) compared to the non-specific and cannot be found the amount of mutant p53 protein in pterygium tissue that has received triamcinolone acetate injection is indeed related to before receiving triamcinolone acetate injection. In this study there were also no measurements that occurred after performing surgery in both treatment groups.

CONCLUSION

Expression of protein p53 mutant in group of pterigium patient who received injection of triamcinolone acetate 0% and in group of pterigium patients who did not get injection of triamcinolone acetate for 5 (33.33%) Expression of protein p53 mutant in group of pterigium patients injection of triamcinolone acetate was lower than pterygium group without injection of
triamcinolone acetate (p = 0.018, two tail). Further requirements with larger and longer samples can be used to determine whether there is a better and better risk than those that can be used for surgery. Make histopathological examination and Imuno Histo Chemical Examination as a postoperative operational standard to monitor and prevent recurrence hazards.
